Abstract

A pot experiment was conducted to evaluate the effects of zinc and vermicompost on the growth, yield and nutrient content of soybean (*Glycine max* L.) plant. The treatment variables were control (-Zn and -VC), VC 5 ton/ha, Zn 1 kg/ha, Zn 2 kg/ha, Zn 3 kg/ha, Zn 1 kg/ha + VC 5 ton/ha, Zn 2 kg/ha + VC 5 ton/ha and Zn 3 kg/ha + VC 5 ton/ha. Application of zinc and vermicompost showed a significant effect on the growth parameters and macro- and micronutrients uptake by the plant. The highest average plant height (164 cm), leaf number (80 nos./plant), leaf area (3360 cm²/plant), fresh weight (49.03 gm/plant), dry weight (24.54 gm/plant), fruit length (9.4 cm), fruit number per plant (5 nos. /plant) were recorded for Zn 1 kg/ha + VC 5 ton/ha treatment while the lowest values were observed in control at harvest. Results of the growth parameters varied significantly ($p \leq 0.05$) with time. It was observed that, the overall best growth performance was achieved in Zn 1 kg/ha + VC 5 ton/ha.

Introduction

Soybean (*Glycine max* L.) is a legume species, widely grown for its edible bean, which has numerous uses. Soybean products, such as textured vegetable protein are ingredients in many meat and dairy substitutes⁽¹⁾. The beans contain significant amount of phytic acid, dietary minerals and B vitamins. The main countries growing soybeans are the United States (32% of world total) (2016 forecast), Brazil (31%) and Argentina (18%). The global production of soybeans is forecasted to be 337 million tons in 2017-2018, The United States, Brazil and Argentina are the world's largest soybean producers and represent more than 80% of global soybean production⁽²⁾. In 2016, the average worldwide yield for soybean crops was 2.8 tons per hectare. In Bangladesh, soybean is mainly cultivated in Noakhali and Laxmipur. Also it is now projected to produce soybean in many districts of Bangladesh.

Like some other crops of long domestication, the relationship of the modern soybean to wild-growing species can no longer be traced with any degree of certainty⁽³⁾. It is a cultural variety with a very large number of cultivars⁽⁴⁾. Soybeans grow in distinct

*Author for correspondence: <tasnimtarannum19@gmail.com>.

morphological stages as they develop from seeds into fully mature plants. Like many legumes, soybeans can fix atmospheric nitrogen by symbiotic bacteria from the Rhizobia group. Together, protein and soybean oil content account for 56% of dry soybeans by weight (36% protein and 20% fat). The remainder consists of 30% carbohydrates, 9% water and 5% ash. Soybeans comprise approximately 8% seed coat or hull, 90% cotyledons and 2% hypocotyl axis or germ⁽⁵⁾.

The origin of soybean is reported to be eastern Asia or China. Globally, soybean has ranked first amongst various oilseed crops, contributing approximately 25% to the world's total oil and fat production. The world's soybean area, production and productivity are 101.81 ha, 253.38 million tones and 2.5 tones/ha, respectively. Given normal weather conditions, soybean production is expected to increase 1.96 per cent to 156 thousand MT in 2017/18 (July - Jun). Among oilseeds in Bangladesh, in 2015-2016 soybeans are the fourth crop in terms of total planted area at 9% of total oilseed planted area⁽²⁾.

Soybean has a very good adaptability towards a wide range of soils and climate. It requires an optimum temperature of 26 to 30°C, the crop does not grow if the temperature falls below 10°C and above 40°C the growth, flowering and seed formation are affected. It is a short day plant and sensitive to photoperiods. The best type of soil is sandy loam having good organic manure content. Soils with a normal pH of 7 and a fair degree of water retention capacity are, however, better suited for its cultivation. It is grown on slopes, Jhum land, terraces and plains. It is a potential crop of the region and is grown primarily as a pulse crop as well as intercrop with maize, ragi, arhar etc.

Since no single source is enough to meet the needs of all the plant nutrients, integrated use of all the sources, namely organic manures, fertilizers and bio-fertilizers needs careful attention. Soybean responds well to both organic and inorganic fertilizers. Like other leguminous crops, requirement of nitrogen is substantially fulfilled from symbiotic nitrogen fixation through rhizobium i.e. 125 - 150 kg N/ha is utilized⁽⁶⁾ and leaves about 30 - 40 kg N/ha for the succeeding crop. They help in nodule formations in legume crops which in turn fixed atmospheric nitrogen needed for their growth.

A limited number of work has been done on interactions of fertilizers particularly of vermicompost and zinc on growth of soybean. Hence, an experiment was conducted to evaluate the effect of vermicompost and zinc on growth of soybean.

Materials and Methods

Surface soil sample (0 - 15 cm) was collected from Dhamrai, Savar. The sample was air-dried, ground and sieved through 2 mm sieve. Soil had a pH of 7.54 (1 : 2.5 w/v H₂O)⁽⁷⁾, electric conductivity (49.9 ds/m) (1 : 5 w/v H₂O)⁽⁷⁾, organic carbon 0.156%⁽⁸⁾, organic matter 0.27%⁽⁷⁾, available nitrogen 0.016% (Kjeldahl extraction)⁽⁷⁾, available phosphorus 0.042% (blue color method using ascorbic acid)⁽⁹⁾, exchangeable potassium

0.030%⁽¹⁰⁾, available sulfur 0.0048% (Turbidimetric method)⁽¹¹⁾, sand 4.66%, silt 68.33% and clay 27.01%, textural concentrations of total iron (2310 mg/kg), manganese (421 mg/kg), zinc (75 mg/kg) and copper (26 mg/kg) were determined using an atomic absorption spectrophotometer (VARIAN AA240).

Fig. 1. *Glycine max* plants: (a) General view of pots, (b) fruit at harvest.

A pot experiment was conducted at the net house of the premises of Department of Soil, Water and Environment, University of Dhaka during Kharif season (Mid-August of 2018 to December of 2018). Seeds (Var. Shohag) were collected from BARI, Joydebpur, Gazipur. This experiment was evaluated in replicated trial with 3 replications and 8 particular treatments. Eight treatments with 3 replications were as follows: Control (–Zn and –VC), VC5 ton/ha, Zn 1kg/ha, Zn 2 kg/ha, Zn 3 kg/ha, Zn 1 kg/ha + VC 5 ton/ha, Zn 2 kg/ha + VC 5 ton/ha and Zn 3 kg/ha + VC 5 ton/ha. The experiment was conducted by following Completely Randomized Design (CRD). Pots of 10 kg capacity were taken and marked in accordance with treatment and replication number providing a drainage in the bottom. Eight kg soil sample was taken in each of the pots. Seed was sown in prepared soil followed by irrigation. Urea, TSP and MP fertilizers was applied in quantities of 20, 15 and 30 kg/ha, respectively in each pot as source of N, P and K. Soils were mixed with vermicompost 5 ton/ha and zinc sulfate 1, 2 and 3 kg/ha, respectively. Vermicompost was collected from Charfession, Bhola district. Total N, P and K contents of vermicompost were 1.10, 0.29 and 0.82%, respectively. Certified seeds of soybean (*Glycine max* L.) were collected from 'Quality Seed Company', Siddique Bazar, Dhaka. Three healthy seeds were sown in each pot and water was applied up to field capacity. One healthy seedling was kept in each pot. The pots were watered thrice a week in the morning. The number of leaves, height and leaf area per plant were recorded at 15 days interval up to 120 days. Fruit number and length were measured and recorded during the harvest of soybean at 120 days.

Soybean was harvested after 120 days from the date of germination of seeds. All crops were uprooted and the roots were washed with distilled water to remove any adhering particles on the root surface. The collected plants were separated into different parts like roots, stems, leaves and fruits. The fresh weights of the samples were taken.

After that the samples were oven dried at 65°C for 48 hours that previously packed in envelopes and then oven dry weight was taken. The dried samples were then ground separately and preserved in plastic bottles for chemical analysis. LSD test of the results was performed using IBM SPSS, version 25.

Results and Discussion

Plant growth was observed in terms of plant height (Table 1), leaf number (Table 2), leaf area (Table 3), fresh and dry weight of leaf, stem, root and fruit (Table 4). Height (cm) values of 15, 30, 45, 60, 75, 90, 105 and 120 days increased significantly ($p \leq 0.05$) (Table 1). During the experiment the maximum plant height (164.0 cm) was observed in Zn 1 kg/ha + VC 5 ton/ha after 120 days of growth. But a remarkable height was observed in VC 5 ton/ha (156 cm) and Zn 2 kg/ha (150 cm). The minimum plant height (45 cm) was recorded in control after 120 days of growth. Chemical fertilizer offers nutrients which are readily soluble in soil solution and thereby instantaneously available to plants. Nutrient availability from organic sources is due to microbial action and improved physical condition of soil. Results of this experiment are in agreement with some other workers⁽¹⁴⁾.

Table 1. Plant height (cm) for different dose of Zn and vermicompost of soybean with continuous interval of days from seed germination to harvest.

| Treatment | Days after sowing | | | | | | | |
|--------------------------|-------------------|-------|-------|-------|-------|-------|-------|-------|
| | 15 | 30 | 45 | 60 | 75 | 90 | 105 | 120 |
| Control (-Zn and -VC) | 5.4 | 7.3 | 13.0 | 15.3 | 18.6 | 22.8 | 32.0 | 45.0 |

Number of leaves per plant has a direct bearing effect on the growth of crops. As shown in (Table 2) the number of leaves per plant varied significantly ($p \leq 0.05$) and increased with fertilizer dose. Highest number of leaves per plant was produced by Zn 1 kg/ha + VC 5 ton/ha treatment where there was interactive dose of vermicompost and zinc. This is because of the combination of both organic and inorganic fertilizer in suitable dose. The minimum values of leaf number was recorded in control at harvesting.

It is visible that number of leaves during harvest is higher than the number of leaves at day 15, this is because the fact that number of leaves were increasing day by day with the length and growth of the plant. Similar findings were reported by others as well⁽¹⁵⁾.

Table 2. Number of leaves counted for different dose of Zn and vermicompost on soybean with continuous interval of days from seed germination to harvest.

| Treatments | Days after sowing | | | | | | | |
|--------------------------|-------------------|-------|-------|-------|-------|-------|-------|-------|

Leaf area is a measure of size of assimilatory system of plant and is a product of leaf length and width. It is also one of the major characteristics influencing plant productivity and is an important determinant of dry matter production and grain yield. Application of fertilizer significantly ($p \leq 0.05$) influenced leaf area of soybean in (Table 3). Data during harvest showed that the highest leaf area (3360 cm²) was recorded in Zn 1 kg/ha + VC 5 ton/ha. The lowest value of leaf area (408 cm²) was observed in control. It is because of the combined dose of vermicompost and ZnSO₄. Result is in agreement with other workers⁽¹⁶⁾.

Fruit number and length are an important yield contributing parameter of soybean. Fruit number and fruit length (cm) were recorded as 1 and 2.1, 3 and 7.0, 2 and 6.5, 2 and 7.1, 1 and 4.6, 5 and 9.4, 4 and 8.3, 2 and 7.7 in the treatments control (-Zn and -VC), VC 5 ton/ha, Zn 1 kg/ha, Zn 2 kg/ha, Zn 3 kg/ha, Zn 1 kg/ha + VC 5 ton/ha, Zn 2 kg/ha + VC 5 ton/ha and Zn 3 kg/ha + VC 5 ton/ha, respectively. Results of the average fruit number and fruit length per plant of soybean during harvest varied significantly ($p \leq 0.05$). The maximum amount of fruit number (5 nos/plant) was observed in Zn 1 kg/ha + VC 5 ton/ha. The second highest value fruit number was (4 nos/plant) was observed in Zn 2 kg/ha + VC 5 ton/ha. The minimum number of fruits (1 nos/plant) was found in control. The maximum fruit length (9.4 cm) was observed in Zn 1 kg/ha + VC 5 ton/ha treatment. The second highest value of fruit length (8.3 cm) was found in Zn 1 kg/ha + VC 5 ton/ha. The minimum fruit length was found in control.

Table 3. Leaf area (cm²) for different dose of Zn and vermicompost on soybean with continuous interval of days from seed germination to harvest.

The yields of fresh and dry weights of leaf, stem, root and fruit are presented in (Table 4). The values for leaf, stem, root and fruit varied significantly ($p \leq 0.05$) for both fresh and dry weights in most of the treatments. The highest yield was obtained due to combined application of organic and inorganic fertilizer which is Zn 1 kg/ha + VC 5 ton/ha treatment. The fresh yields were 8.03, 15.55, 17.54 and 6.91 g/plant and dry weight values were 3.84, 7.97, 7.98 and 4.75 g/plant on day 120 after harvest, respectively. The minimum values for fresh weights were 3.42, 3.61, 4.92 and 0.82 g/plant and for dry weights were 3.58, 3.44, 4.26 and 0.73 g/plant for leaf, shoot, root and fruit, respectively found in control.

Table 4. Fresh and dry weights for different doses on soybean in root, shoot, leaf and fruit.

| Treatments | Fresh weight (g/plant) | | | | | Dry weight (g/plant) | | | | |
|--------------------------|------------------------|-------|-------|-------|-------|----------------------|-------|-------|-------|-------|
| | Root | Shoot | Leaf | Fruit | Total | Root | Shoot | Leaf | Fruit | Total |
| Control(-Zn and - VC) | 3.42 | 3.61 | 4.92 | 0.82 | 12.77 | 3.58 | 3.44 | 4.26 | 0.73 | 12.01 |

The experiment reported here is primarily concerned with the growth response and both fresh and dry matter yield of soybean (*Glycine max* L.) plants influenced by different treatments of zinc and vermicompost manure. It revealed that different growth parameters have been influenced by the combined application (inorganic + organic) fertilizers. In most of the cases combined application of fertilizers increased the growth parameters, but the treatment T₆ (Zn 1 kg/ha + VC 5) has shown the best result than the other treatments where the zinc fertilizers were applied in higher doses. This signifies that the inorganic fertilizers need to be used carefully according to soil health and crop need. If it does, more positive interactive effects of inorganic and organic fertilizers can be possible to get best growth of crops.
