Key words: BARI GOM-26, NAA, Foliar application, Growth analysis

Abstract

Leaf area index (LAI), crop growth rate (CGR), relative growth rate (RGR), net assimilation rate (NAR) and leaf area duration (LAD) of a variety of wheat (*Triticum aestivum* L.) were studied with three concentrations (0, 25 and 50 ppm) of naphthalene acetic acid (NAA) and four levels (0, 50, 75 and 100 %) of N-fertilizer in a field experiment during 2014 - 2015. Results showed that LAI and LAD at all stages of growth increased from control and their peak values were recorded mostly from 25 ppm NAA in combination with 75 % N-fertilizer and 50 ppm NAA in combination with 50% N-fertilizer. RGR was affected both positively and negatively depending on the concentration of NAA and nitrogen levels and was higher at earlier age (15 to 45 DAS) as opposed to later stage irrespective of treatments. CGR and NAR were also affected positively and negatively and tended to increase sharply reaching maximum at 30 - 45 DAS with a few exceptions and then decreased for most of the treatments with the progression of age. At 30 - 45 DAS, peak value of CGR was recorded from 25 ppm NAA in combination with 75% N-fertilizer. Of all the treatments, 25 ppm NAA in combination with 75% N-fertilizer produced better stimulation.

Introduction

The classical concept of physiological basis of variation in crop yield nourishes the idea that the differences in crop yield in an environment is the ultimate reflection of variation in different growth processes of the successive stages of crop development. Such variations in growth processes can be efficiently measured by quantifying the different components of growth, collectively known as growth analysis⁽¹⁻³⁾. A combination of these growth components not only states how plant accumulates dry matter, but also reveals the events which can make a plant more or less productive singly or in population⁽⁴⁾. Crop growth processes viz., CGR, RGR and NAR control dry matter production and ultimately reflected in the yield^(5,6). LAI and LAD are important morphological index of plant leaf which are closely connected with photosynthetic activity of leaves and control dry matter production⁽⁷⁾. NAA, a synthetic growth

*Author for correspondence: <jahan.nargis@yahoo.com>.

regulator, at appropriate concentration has proved its potentiality to substantially influence these growth parameters in different plants *viz.*, chickpea⁽⁸⁾, rice⁽⁹⁾. Use of N-fertilizer is also important for proper growth and development. But, recently fertilizer management has drawn the attention of plant scientists all over the world. NAA in combination with nitrogen fertilizer can be an important way to serve this purpose. A report regarding their combined effects on plant growth is also available⁽¹⁰⁾. However, growth and growth attributes of wheat in relation to NAA at different nitrogen fertilizer levels are yet to be available in Bangladesh. Thus, an attempt was made to evaluate the effect of NAA at different nitrogen levels on some growth parameters of BARI GOM-26.

Materials and Methods

A field experiment was carried out at the Botanical Garden of the Department of Botany, University of Dhaka during November, 2014 to March, 2015. The experimental soil was analyzed and high levels of phosphorus and low levels of nitrogen and potassium were recorded⁽¹¹⁾. Cow-dung, TSP, MP and gypsum were applied as basal dose during land preparation. The experiment was laid out in RCBD with five replications. Seeds of BARI GOM-26 were collected from Bangladesh Agricultural Research Institute (BARI), Joydebpur, Gazipur. The experiment comprised of 12 treatment combinations where, three concentrations of NAA *viz.*, without NAA (G_0), 25 ppm NAA (G_1) and 50 ppm NAA (G_2), and four levels of N-fertilizer *viz.*, without any N-fertilizer (F_0), 50% of the recommended dose (F_1), 75% of the recommended dose (F_2) and full recommended dose of urea (F_3) were used. Two-thirds of the urea were used as basal and the rest one-third was applied at 25 days after sowing. Seeds were sterilized with 0.05% calcium hypochlorite solution for five minutes and repeatedly washed in tap water and finally with distilled water to remove any trace of calcium hypochlorite. Seeds were sown on November 8, 2014. Weeding was done at the age of 18 days followed by thinning to keep plant to plant distance of 10 cm. Irrigation was also done as and when necessary. NAA treatments were applied as foliar spray at the age of 30 days.

Data on leaf area index (LAI), leaf area duration (LAD), crop growth rate (CGR), relative growth rate (RGR) and net assimilation rate (NAR) were recorded from the age of 15 days after spray (DAS) up to 75 DAS at an interval of 15 days. Leaf area (LA) was measured by length width method according to Voldeng and Simpson⁽¹²⁾. LAI, CGR, LAD were calculated following the formula of Yoshida *et al.*⁽¹³⁾, Watson⁽¹⁴⁾ and Power *et al.*⁽¹⁵⁾, respectively. RGR and NAR were calculated using the formula of Williams⁽¹⁶⁾. Data were analyzed statistically⁽¹⁷⁾ and treatment means were compared by LSD test at 5% level of significance.

Results and Discussion

Results presented in Table 1 revealed that leaf area index (LAI) increased in all the treatments from the control (G_0F_0) at all the ages and was significantly affected at 15, 30 and 45 DAS. Application of 50 ppm NAA in combination with 50% N-fertilizer resulted in the maximum LAI at 15, 60 and 75 DAS, respectively whereas maximum LAI at 30 and 45 DAS were found due to 25 ppm NAA in combination with 75% N-fertilizer. Application of N-fertilizer alone gave higher leaf area index as compared with NAA application alone. Increase in LAI following NAA and N-fertilizer application has also been reported in paddy⁽¹⁰⁾. Patil *et al.*⁽¹⁸⁾ obtained higher LAI in chickpea with 20 ppm NAA. Karim and Fattah⁽⁸⁾ reported both increase and decrease in LAI following NAA application in chickpea.

LAD describes the total amount of leaf area present over a particular period of growth and is directly correlated with dry matter production. It has been observed that any practice that increases the longevity of green leaves should increase the dry weight of plants. Table 2 revealed that application of NAA at different nitrogen levels significantly affected LAD throughout the investigation period except at 60 - 75 DAS. LAD increased over the control at all the growth ages. At 15 - 30 and 60 - 75 DAS maximum LAD values were found due to 50 ppm NAA in combination with 50% N-

fertilizer. Whereas, at 30 - 45 and 45 - 60 DAS significantly highest LAD was obtained from 25 ppm NAA in combination with 75 % N-fertilizer. LAD showed an increasing trend as the plants aged except due to G₀F₁ and G₀F₂ at 60 - 75 DAS. Increase in LAD following NAA application was also reported in chickpea by Karim and Fattah⁽⁸⁾ and in okra by Surendra *et al.*⁽¹⁹⁾.

Fig. 1 showed that CGR was higher at the initial stage of growth and then declined till maturity. CGR was affected both positively and negatively and showed substantial differences over the growth stages. CGR increased sharply at 30 - 45 DAS following all the treatments except G₁F₀, G₂F₀ and G₂F₂ as against control. Reduction in crop growth rate with plant age was probably due to cessation of vegetative growth, loss of leaves, and senescence. The peak crop growth rate was recorded at 15 - 30 and 30 - 45 DAS from 25 ppm NAA in combination with 75% N-fertilizer. Similar results of increase and decrease in CGR following NAA application was reported in chickpea⁽⁸⁾.

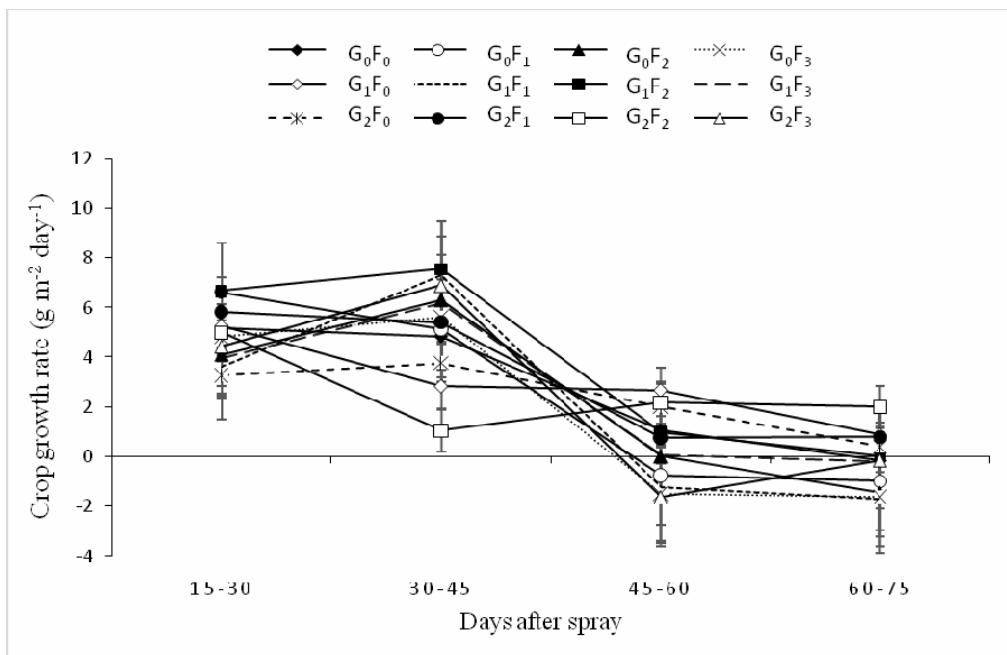

Fig. 1. Effect of NAA at different nitrogen levels on crop growth rate ($\text{g}/\text{m}^2/\text{day}$) of BARI GOM-26 at different days after spray (Mean \pm SE).

Irrespective of the treatments, RGR was more at early stage (15 to 45 DAS) and showed a decreasing trend with the advancement of plant age (Fig. 2). The decrease in RGR was probably due to the increase in metabolically active tissue, which contributed less to the plant growth. It has also been suggested that the decrease in RGR could be attributed to shading of lower leaves by upper leaves⁽²⁰⁾. Variations in RGR across the treatments were not apparent in the later growth period, but the differences were

were recorded from 50% N-fertilizer alone and 25 ppm NAA in combination with 50% and 75% N-fertilizer, respectively. RGR increased over the control due to all the treatments except G₁F₂ during the period from 60 - 75 DAS. Jahan and Adam⁽⁹⁾ also reported higher RGR following NAA application at the early stages of growth for rice.

NAR represents plant photosynthetic efficiency. NAR was high in the earlier stages (15 - 30 DAS and 30 - 45 DAS) and thereafter decreased with advancement in the age of the crop (Fig. 3). The decrease in NAR at later stages of growth could be attributed to shading of lower leaves and increase in the number of older leaves which lost photosynthetic efficiency. At 30 - 45 DAS, NAR increased due to all the treatments from control except G₁F₀, G₂F₀ and G₂F₂ and reached peak due to 25 ppm NAA in combination with 75% N-fertilizer (G₁F₂). During 60 - 75 DAS, however, the only decrease was recorded due to G₁F₂ treatment. Both increase and decrease in NAR following NAA application has also been reported in rice by Jahan and Adam⁽⁹⁾ and in chickpea by Karim and Fattah⁽⁸⁾.

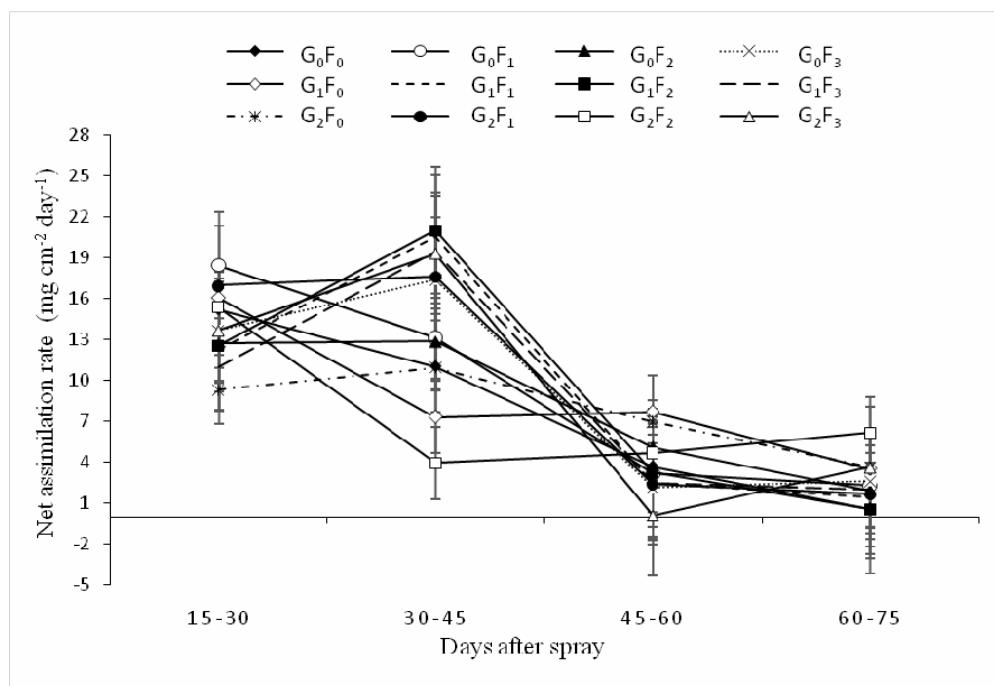

Fig. 3. Effect of NAA at different nitrogen levels on net assimilation rate ($\text{mg}/\text{cm}^2/\text{day}$) of BARI GOM-26 at different days after spray (Mean \pm SE).

The overall results of this investigation showed that NAA had both stimulatory and inhibitory effect on growth efficiency of plants and plants treated with NAA in combination with lower doses of N-fertilizer had higher LAI, CGR, RGR, NAR and LAD.

Thus, lower doses of N-fertilizer along with foliar application of NAA could be as much effective as higher doses (100%) of N-fertilizer application to increase growth and development of plants with higher values of physiological characteristics.
